#### Q54 English

Read the passage carefully and answer the questions that follow.

Cushing's syndrome happens when there is too much cortisol in the body over a long period. Cortisol is produced by the adrenal glands and helps control blood pressure, metabolism, immunity, and the body's response to stress. When cortisol remains high, it affects many organs. The most common cause is long-term use of steroid medicines prescribed for asthma, autoimmune diseases, arthritis, or after organ transplants. This is called exogenous Cushing's syndrome.

In endogenous Cushing's syndrome on the other hand, the body produces excess cortisol on its own. This is usually due to a non-cancerous tumour in the pituitary gland (called Cushing's disease). The pituitary gland is a small gland located at the base of the brain. Less commonly, it may be caused by tumours in the adrenal glands or by tumours elsewhere in the body that produce ACTH, a hormone normally released by the pituitary gland.

Choose the most appropriate title for the passage.

A. Causes and Types of Cushing's Syndrome Explained
